Equipment Monitoring Dashboard — Technical Overview

Target document B | Synthetic example for checking required content

1. Overview

The dashboard helps maintenance staff monitor equipment condition and identify developing problems before they interrupt daily operations. It is designed for the monitoring station and does not control the equipment's physical operation.

2. Main Capabilities

The application collects readings from connected sensors, displays current status, and stores historical measurements so staff can review changes over time.

3. Connections

Operators use a web browser to view the dashboard. Sensor readings arrive from a gateway connected to the equipment.

The document does not specify the communication protocol or list the full set of external software interfaces.

4. Fault Response

If a sensor stops sending readings, the dashboard displays a warning and marks that sensor's status as unavailable. The document does not explain recovery steps or other hazard responses.

5. Deployment

The dashboard is intended to be straightforward to use and should respond quickly during normal operation.

No numeric response-time target, capacity limit, or explicit acceptance threshold is provided.

6. Validation

During testing, an operator will confirm that live readings appear, historical values can be opened, and a warning is shown when a sensor connection is lost.

Designed test intent: purpose/scope and core functions are stated clearly; interfaces and fault handling have omissions; measurable acceptance criteria are absent; testing is described.
